

## Geometric Applications of BSTs

### 1) 1D range search

#### Geometric Objects

- extension of the ordered symbol table

- insert key-value pair

- search for key  $k$

- delete key  $k$

- range search: find all keys between  $k_1$  and  $k_2$

- range count: no. of keys between  $k_1$  and  $k_2$

- Application: database queries

• Geometric interpretation

- keys are a point on line

- find / count points in a given 1d interval

## Implementations

- ~~unordered~~ array - fast insert, low range search  $O(1)$
- ordered array - slow insert, binary search for  $(k_1)$  and  $(k_2)$  to do range search  $O(N)$
- Size = rank(high) - rank(low) + 1  
range count if high

## range search

- recursively find all keys in left subtree (if any could fall in range)
- check key in current node
- recursively find all keys in right subtree

## II) Line segment intersection

- given  $N$  horizontal and vertical line segments, find all intersections

\* quadratic algorithm  $\Rightarrow$  check all pairs of line segments for intersection

\* all  $(x-)$  and  $(y-)$  coordinates are distinct

### Sweep-line algorithm

- Sweep vertical line from left to right

- $x$ -coordinates define events

- h-segment (left endpoint) : insert  $y$ -coordinate into BST

- horizontal segment (right endpoint) :

remove  $y$ -coordinate from BST

- vertical segment : range search for interval of  $y$ -endpoints

$O(N \log N + R)$  to find all  $R$  intersections

### III) kd-Trees

- extension of ordered symbol-table to 2d keys

- insert a 2D key / delete

- search for a 2D key

- range search: find all keys that lie in a 2D range

- range count: no. of keys that lie in a 2D range

- keys are points in a plane

- find/count points in a given h-v rectangle

\* divide space into  $M$  by  $M$  grid of squares

↳ add points to a square

$M \times M \Rightarrow M$  too large  $\Rightarrow$  waste of space

$O(M^2 + X)$  - space

$\Rightarrow M$  too small  $\Rightarrow$  too many points

per square  $\Rightarrow$  waste of time

$O(1 + X/M^2)$  - time

$$\Rightarrow \boxed{M = \sqrt{N}} \Rightarrow \boxed{\text{problem} = \text{clustering}}$$

\* Use a tree to represent a recursive sub-division of a plane

grid

Quad-tree

rec. divide space  
into 4 quadrants

2d tree

rec. div. space  
into 2 half  
planes

2D tree

plane

tree level - start with vertical  $\Rightarrow$  switch  
at every level

\* Data structure  $\Rightarrow$  BST but alternate  
using x- and y-coordinates as keys

◦ Range search

◦ recursively search  $\left\{ \begin{array}{l} \text{left-bottom (if} \\ \text{any could fall in} \\ \text{rectangle)} \\ \text{right-top} \end{array} \right.$

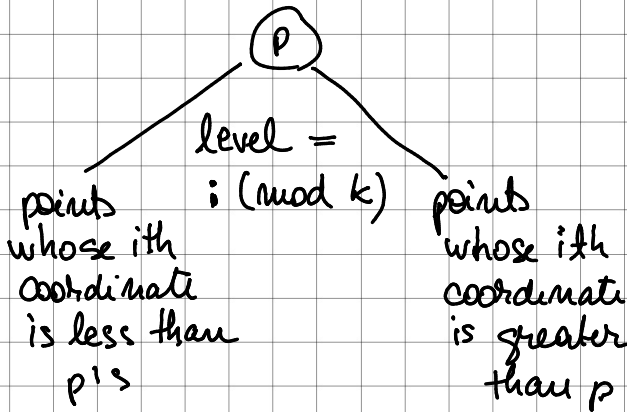

- typical  $\boxed{R + \log N}$ ,  $R = \text{no. of points}$   
worst  $R + \sqrt{N}$  in range

◦ find closest point to query point

◦ compute distance from query to  
current point (save as min)

## k-d tree

- recursively partition k-dimensional space into 2 half-spaces
- implementation: BST, but cycle through dimensions like 2D trees

## IV) Interval Search Trees

1-D interval search = data structure to hold a set of (overlapping) intervals

- insert an interval (low, high)
- search
- delete

o interval intersection query: given an interval  $(low, high)$  find all intervals in data structure that intersects  $(low, high)$

class IntervalSearchTree

put (key low, key high, value)

get (key low, key high)

delete (key low, key high)

intersects (key low, key high)

\* no two intervals have the same left endpoint

\* use left endpoint as BST key

\* store max endpoint in subtree rooted at node

---

search: 1) if interval in node intersects query interval return it

- else if left subtree is null, go right
- else if max endpoint in left subtree is less than low  $\Rightarrow$  go right
- else go left

$\Rightarrow$  use Red-Black BST for performance

## V) Rectangle Intersection

- find all intersections among a set of orthogonal rectangles
- all coordinates are distinct
  - sweep vertical line from left to right
  - x-coordinates of left and right endpoints define events
  - maintain set of rectangles that intersect the sweep line in an interval search tree (using y intervals of rectangle)
  - left endpoint: interval search for y interval of rectangle

insert  $y$ -interval

- right endpoint - remove  $y$  interval
